Preface

Before 19th century, theory of limits, infinite series, differentiation, and integration was so focused on calculating particular values of expressions, such as infinite series, that they do not have sufficient rigor. As an example, A. L. Cauchy, a pioneer of mathematical analysis, is known to have made many mistakes on his theses. Thereby, establishing a rigid framework for analysis has emerged as one of the central problems of mathematics in 19th century.

CHAPTER 1

Real numbers

1. Fields

2. Orders

3. Norms

4. Completeness

5. The real numbers

5.1. Constructions of the real numbers.

5.2. Cardinality.

5.3. Elementary functions.

CHAPTER 2

Sequences

CHAPTER 3

Functions

CHAPTER 4

Integration

1. Lebesgue spaces

1.1. $1 \leq p \leq \infty$.

DEFINITION 1.1. Let f be a measurable real-valued function on a measure space (X, μ) . The L^p norm of f is defined as a real number

$$\|f\|_{L^p(X)} := \left(\int |f|^p d\mu \right)^{\frac{1}{p}}$$

for $0 < p < \infty$, and

$$\|f\|_{L^\infty(X)} := \operatorname{ess\,sup}_{x \in X} |f(x)|$$

for $p = \infty$.

DEFINITION 1.2. The *essential supremum* is defined by the smallest number M such that

$$|f(x)| \leq M \quad a.e.$$

We often abbreviate $\|f\|_{L^p(X)}$ as $\|f\|_{L^p}$ or $\|f\|_p$.

1.2. L^2 space.

CHAPTER 5

Multivariable calculus

1. Picard-Lindelöf theorem

THEOREM 1.1. *Consider the following initial value problem:*

$$x' = f(t, x), \quad x(0) = x_0,$$

where

$$f(-, x) \in C([0, T]), \quad f(t, -) \in \text{Lip}(\overline{B(x_0, R)}).$$

If T and R satisfy

- (1) $TK < 1$,
- (2) $TM \leq R$,
- (3) $|f(t, x)| \leq M$ on $[0, T] \times \overline{B(x_0, R)}$,

then the equation has a unique solution on $[0, T]$.

PROOF. Define $\varphi : C([0, T], \overline{B(x_0, R)}) \rightarrow C([0, T], \overline{B(x_0, R)})$ as:

$$\varphi(x)(t) := x_0 + \int_0^t f(s, x(s)) ds.$$

It is well-defined since

$$\begin{aligned} |\varphi(x)(t) - x_0| &\leq \int_0^t |f(s, x(s))| ds \\ &\leq TM \leq R. \end{aligned}$$

It is a contraction since we have

$$\begin{aligned} |\varphi(x)(t) - \varphi(y)(t)| &\leq \int_0^t |f(s, x(s)) - f(s, y(s))| ds \\ &\leq \int_0^t K|x(s) - y(s)| ds \\ &\leq TK \sup_s |x(s) - y(s)| \end{aligned}$$

so that

$$\|\varphi(x) - \varphi(y)\| \leq TK\|x - y\|$$

□

1.1. Inverse function theorem.

PROOF 1. Take y . We must first define x such that $f(x) = y$. Let

$$\varphi_y(x) = x + df_p^{-1}(y - f(x)).$$

Note that $f(x) = y$ if and only if x is a fixed point of φ_y .

Since df is continuous, there is an open ball U such that

$$\|df(x) - df(p)\| < \frac{1}{2\|df(p)^{-1}\|}.$$

For $x \in U$,

$$d\varphi_y(x) = \text{id} - df_p^{-1}df_x$$

□
