

Measure theory

IKHAN CHOI

1. MEASURE CONSTRUCTION

1.1. Boolean algebra.

Definition 1.1. Let X be a set. A *ring of sets* is a family of subsets of X that is closed under finite union and finite relative complement; in other words, $\mathcal{R} \subset \mathcal{P}(X)$ is called a ring of sets if the following two conditions are satisfied:

- (1) if $A, B \in \mathcal{R}$, then $A \cup B \in \mathcal{R}$,
- (2) if $A, B \in \mathcal{R}$, then $A \setminus B \in \mathcal{R}$.

Proposition 1.1. Let X be a set and $\mathcal{R} \in \mathcal{P}(X)$. Then, the followings are equivalent:

- (1) \mathcal{R} is a ring of sets,
- (2) \mathcal{R} is closed under symmetric difference and finite intersection,
- (3) $(\mathcal{R}, \Delta, \cap)$ is a pseudo-ring,
- (4) $(\mathcal{R}, \Delta, \cap)$ is a Boolean ring.

Remark (IMPORTANT REMARK). In measure theory, we require an additional condition that the entire set X can be covered by a countable set of elements for a ring of sets.

If a ring of sets contains a multiplicative identity, the entire set, then we call the ring of sets as follows:

Definition 1.2. A *field of sets* or an *algebra of sets* is a ring of sets with the entire set.

Proposition 1.2. Let X be a set and $\mathcal{A} \in \mathcal{P}(X)$. Then, the followings are equivalent:

- (1) \mathcal{A} is an algebra of sets,
- (2) \mathcal{A} is closed under finite union, finite intersection, and complement,
- (3) \mathcal{A} is a Boolean algebra.

Definition 1.3 (Premeasure and measure). Let X be a set and \mathcal{R} be a ring of sets over X . A *premeasure* is a set function $\mu : \mathcal{R} \rightarrow [0, \infty]$ such that

- (1) $\mu(\emptyset) = 0$, (null empty set)
- (2) $\mu(\bigcup_{i=1}^{\infty} E_i) = \sum_{i=1}^{\infty} \mu(E_i)$ for a sequence of disjoint sets $\{E_i\}_i \in \mathcal{R}$. (countable additivity)

A *measure* is a premeasure on a σ -algebra.

Definition 1.4. Let X be a set. An *outer measure* is a set function $\mu^* : \mathcal{P}(X) \rightarrow [0, \infty]$ such that

First Written : November 10, 2019.

Last Updated : November 10, 2019.

- (1) $\mu^*(\emptyset) = 0$, (null empty set)
- (2) if $E \subset E'$, then $\mu^*(E) \leq \mu^*(E')$, (monotonicity)
- (3) $\mu(\bigcup_{i=1}^{\infty} E_i) \leq \sum_{i=1}^{\infty} \mu(E_i)$ for a sequence of disjoint sets $\{E_i\}_i \in \mathcal{R}$. (countable subadditivity)

1.2. Carathéodory's extension theorem. Let $\sigma(\mathcal{R})$ be the σ -algebra generated by \mathcal{R} .

Theorem 1.3 (Carathéodory's extension theorem). *Every premeasure on \mathcal{R} can be extended to a measure on $\sigma(\mathcal{R})$.*

Proof. (\Leftarrow)

Step 1: Construction of an outer measure. Let μ be a premeasure on a ring \mathcal{R} . We claim that a set function $\mu^* : \mathcal{P}(X) \rightarrow [0, \infty]$ defined as

$$\mu^*(E) := \inf \left\{ \sum_{i=1}^{\infty} \mu(E_i) : E \subset \bigcup_{i=1}^{\infty} E_i, E_i \in \mathcal{R} \right\}$$

is an outer measure. Since we can easily check that μ^* has a null empty set and monotonicity, we will show the countable subadditivity.

Step 2: Construction of a σ -algebra. Let μ^* be the associated outer measure of the premeasure μ .

Step 3: Outer measurability of the ring.

Step 4: Countable additivity of restricted outer measure.

□

Proposition 1.4. *If μ is σ -finite, then any extension of measure is unique.*

2. MEASURES FOR PROBABILITY THEORY

Since $\{f_n(x)\}_n$ diverges if and only if

$$\exists k > 0, \quad \forall n_0 > 0, \quad \exists n > n_0 : \quad |f_n(x) - f(x)| > \frac{1}{k},$$

we have

$$\begin{aligned} \{x : \{f_n(x)\}_n \text{ diverges} \} &= \bigcup_{k>0} \bigcap_{n_0>0} \bigcup_{n>n_0} \{x : |f_n - f| > \frac{1}{k}\} \\ &= \bigcup_{k>0} \limsup_n \{x : |f_n - f| > \frac{1}{k}\}. \end{aligned}$$

Since for every k we have

$$\begin{aligned} \limsup_n \{x : |f_n - f| > \frac{1}{k}\} &\subset \limsup_{n>k} \{x : |f_n - f| > \frac{1}{n}\} \\ &= \limsup_n \{x : |f_n - f| > \frac{1}{n}\}, \end{aligned}$$

we have

$$\{x : \{f_n(x)\}_n \text{ diverges} \} \subset \limsup_n \{x : |f_n - f| > \frac{1}{n}\}.$$

Theorem 2.1. *Let (X, μ) be a measure space. Let f_n be a sequence of measurable functions. If f_n converges to f in measure, then f_n has a subsequence that converges to f μ -a.e.*

Proof. We can extract a subsequence f_{n_k} such that

$$\mu(\{x : |f_{n_k} - f| > \frac{1}{k}\}) > \frac{1}{2^k}.$$

Since

$$\sum_{k=1}^{\infty} \mu(\{x : |f_{n_k} - f| > \frac{1}{k}\}) < \infty,$$

by the Borel-Canteli lemma, we get

$$\mu(\limsup_k \{x : |f_{n_k} - f| > \frac{1}{k}\}) = 0.$$

Therefore, f_{n_k} converges μ -a.e. □

3. TOPOLOGICAL MEASURES

Lemma 3.1 (The Urysohn lemma). *Let X be a LCH. Let K be a compact subset of X and U be an open neighborhood of K . Then, there is $f \in C(X)$ such that*

$$f|_K \equiv 1 \quad \text{and} \quad f|_{U^c} \equiv 0.$$

Lemma 3.2 (The Tietze extension theorem). *Let X be a LCH. Let K be a compact subset of X . For $f \in C(K)$, there is $\tilde{f} \in C(X)$ such that $\tilde{f}|_K = f$.*

Topologies on $C_c(X)$ for LCH X : weaker to stronger

- (1) Topology of compact convergence: $\overline{C_c(X)} = \overline{C_{\text{loc}}(X)} = C_{\text{loc}}(X)$.
- (2) Topology of uniform convergence: $\overline{C_c(X)} = C_0(X)$, $C_c(X)^* = M(X)$.
- (3) Inductive topology: $\overline{C_c(X)} := \text{colim}_{U \in X} C_c(U) = C_c(X)$.

The space $C_{\text{loc}}(X)$ is $C(X)$ as a set and has the topology of compact convergence

Proposition 3.3. *A continuous function is measurable iff the σ -algebra is Borel.*

Proposition 3.4. *Let μ be a Borel measure on a LCH X . Then,*

- (1) μ defines a linear functional $C_c(X) \rightarrow \mathbb{R}$ iff it is locally finite,
- (2) μ is continuous on the inductive topology iff it is locally finite (i.e. always),
- (3) μ is continuous on the uniform topology iff it is finite.

3.1. Regular measures.

Theorem 3.5. *Let μ be a Borel measure. Then, the followings are equivalent:*

- (1) μ is inner regular on σ -bounded sets
- (2) μ is outer regular on σ -bounded sets.

A regular measure of an open set U can be realized by the norm of integration functional on $C_c(U)$.

Lemma 3.6. *Let μ be a Borel measure on a LCH X . Then, μ is inner regular on open sets iff*

$$\mu(U) = \|\mu\|_{C_c^*(U)}$$

for every open U in X .

Proof. (\geq) For $f \in C_c(U)$, we have

$$|\int f d\mu| = |\int_U f d\mu| \leq \mu(U) \|f\|.$$

(\leq) Since μ is inner regular on U , there is a compact set $K \subset U$ such that $\mu(U) - \mu(K) < \varepsilon$ (for the case $\mu(U) = \infty$, we can deal with separately). We can find a nonnegative function $f \in C_c(U)$ with $f|_K \equiv 1$ and $f \leq 1$ by the construction of Urysohn. Then, for all $\varepsilon > 0$ we have

$$\mu(U) < \mu(K) + \varepsilon \leq \int f d\mu + \varepsilon \leq \|\mu\|_{C_c^*(U)} + \varepsilon. \quad \square$$

(\Rightarrow) Let $f \in C_c(U)$ be a function such that $\|f\| = 1$ and

$$\mu(U) - \varepsilon < \int f d\mu.$$

Let $K = \text{supp}(f)$. Then

$$\mu(K) \geq \int f > \mu(U) - \varepsilon.$$

Positivity of linear functional itself implies a rather strong continuity property.

Theorem 3.7. *Let X be LCH. A positive linear functional on $C_c(X)$ is continuous with respect to the inductive topology.*

Proof. Let I be a positive linear functional on $C_c(X)$. We want to show every restriction of I on $C_c(U) \hookrightarrow C_c(X)$ for $U \Subset X$ is continuous for uniform norm.

Choose a nonnegative $\varphi \in C_c(X)$ such that $\varphi|_{\overline{U}} \equiv 1$ using the Urysohn lemma. Then,

$$|I(f)| \leq I(|f|) = I(\varphi|f|) \leq I(\varphi\|f\|) = I(\varphi)\|f\| \lesssim_U \|f\|$$

for $f \in C_c(U)$. \square

3.2. Radon measures. Locally compact Hausdorff spaces have at least two important applications in abstract analysis related to measure theory: one is locally compact groups and the associated Harr measures in abstract harmonic analysis, the other is the Gelfand-Naimark theorem which states every commutative C^* -algebra can be represented as a function space on a locally compact Hausdorff space. In the set of this section, we assume every base space X is locally compact Hausdorff.

Note that locally finite measures are compact finite but the converser holds only if in locally compact Hausdorff spaces. We want to consider locally finite Borel measures as the minimally compatible measures with a given topology on X . For locally finite Borel measures, a set is finite-measured if and only if it is contained in a compact set.

Definition 3.1. A *Radon measure* is a Borel measure on X which satisfies the following three conditions:

- (1) locally finite,
- (2) outer regular on all Borel sets,
- (3) inner regular on all open sets.

Radon measures are rather simply characterized when the base space X is σ -compact. The following proposition proves the equivalence between regularity and Radonness of locally finite Borel measure on a σ -compact space.

Proposition 3.8. *A Radon measure is inner regular on all σ -finite Borel sets. (Folland's)*

Proof. First we approximate Borel sets of finite measure, with compact sets. Let E be a Borel set with $\mu(E) < \infty$ and U be an open set containing E . By outer regularity, there is an open set $V \supset U - E$ such that

$$\mu(V) < \mu(U - E) + \frac{\varepsilon}{2}.$$

By inner regularity, there is a compact set $K \subset U$ such that

$$\mu(K) > \mu(U) - \frac{\varepsilon}{2}.$$

Then, we have a compact set $K - V \subset K - (U - E) \subset E$ such that

$$\begin{aligned} \mu(K - V) &\geq \mu(K) - \mu(V) \\ &> \left(\mu(U) - \frac{\varepsilon}{2}\right) - \left(\mu(U - E) + \frac{\varepsilon}{2}\right) \\ &\geq \mu(E) - \varepsilon. \end{aligned}$$

It implies that a Radon measure is inner regular on Borel sets of finite measures.

Suppose E is a σ -finite Borel set so that $E = \bigcup_{n=1}^{\infty} E_n$ with $\mu(E_n) < \infty$. We may assume E_n are pairwise disjoint. Let K_n be a compact subset of E_n such that

$$\mu(K_n) > \mu(E_n) - \frac{\varepsilon}{2^n},$$

and define $K = \bigcup_{n=1}^{\infty} K_n \subset E$. Then,

$$\mu(K) = \sum_{n=1}^{\infty} \mu(K_n) > \sum_{n=1}^{\infty} \left(\mu(E_n) - \frac{\varepsilon}{2^n}\right) = \mu(E) - \varepsilon.$$

Therefore, a Radon measure is inner regular on all σ -finite Borel sets. \square

We get a corollary:

Corollary 3.9. *If X is σ -compact, then a locally finite Borel measure is Radon if and only if it is regular.*

Theorem 3.10. *If every open set in X is σ -compact (i.e. Borel sets and Baire sets coincide), then every locally finite Borel measure is regular.*

Proposition 3.11. *In a second countable space, every open set is σ -compact (i.e. Borel sets and Baire sets coincide).*

Two corollaries are presented as follows:

Many applications assume X is an open subset of a Euclidean space, so X is usually second countable. In this case, the followings will be synonym: A measure is

(1)

$$L_{\text{loc}}^1 = \text{a.c. measures} \subset \text{LfB measures} \subset \text{Radon measures} \subset \mathcal{D}'.$$

Theorem 3.12. *Every finite Radon measure is regular.*

4. RIESZ-MARKOV-KAKUTANI REPRESENTATION THEOREM

In this section, we always assume X is a locally compact Hausdorff space. Hence we can use the Urysohn lemma in the following way: If a compact subset K and a closed subset F are disjoint, then by applying the Urysohn lemma on a compact neighborhood of K , we can find a continuous function $\varphi : X \rightarrow [0, 1]$ such that $\varphi|_K = 1$ and $\varphi|_F = 0$. In particular, there always exists a “continuous characteristic function” $\varphi \in C_c(X)$ with $\varphi|_K = 1$.

There are two Riesz-Markov-Kakutani theorems: the first theorem describes the positive elements in $C_c(X)^*$ as Radon measures when the natural colimit topology is assumed, and the second theorem describes $C_c(X)^*$ as the space of finite Radon measures when uniform topology is assumed.

Theorem 4.1 (The Riesz-Markov-Kakutani representation theorem). *Let X be LCH. Let I be a positive linear functional on $C_c(X)$. Then, there is a unique Radon measure μ on X such that*

$$I(f) = \int f d\mu.$$

Proof. Step 0: Uniqueness. Let μ be a Radon measure on X . By the local finiteness, $\int f d\mu$ is finite for all $f \in C_c(X)$. Suppose we know the value of $\int f d\mu$ for all $f \in C_c(X)$. By the inner regularity,

$$\mu(U) = \|\mu\|_{C_c^*(U)}$$

is determined for all open U . By the outer regularity,

$$\mu(E) = \inf\{\mu(U) : E \subset U, U \text{ is open}\}$$

is determined for all Borel E . So we are done.

Step 1: Carathéodory construction. Define a set function μ on the topology by

$$\mu(U) := \|I\|_{C_c^*(U)}.$$

If μ is a premeasure, then

$$\mu(E) := \inf\{\mu(U) : E \subset U, U \text{ is open}\}$$

defines a Borel measure by the Carathéodory extension. We only need countable additivity of μ for open sets to show μ is a premeasure.

Step 2: A lemma. Let $f|_K \equiv 1$. For $U = \{x : f(x) > 1 - \varepsilon\}$, there is $g \in C_c(U)$ such that $g \leq 1$ and $I(g) > \mu(U) - \varepsilon$. Then,

$$\mu(K) \subset \mu(U) < I(g) + \varepsilon < \frac{1}{1-\varepsilon} I(f) + \varepsilon$$

implies $\mu(K) \leq I(f)$.

Let $f \leq 1$. There is an open set $U \supset \text{supp}(f)$ such that $\mu(U) < \mu(\text{supp}(f)) + \varepsilon$ since $\text{supp}(f)$ is Borel. For $U \supset \text{supp}(f)$, there is $g \in C_c(U)$ such that $g \leq 1$ and $g|_{\text{supp}(f)} \equiv 1$ by the Urysohn lemma. Then,

$$I(f) \leq I(g) \leq \mu(U) < \mu(\text{supp}(f)) + \varepsilon$$

implies $I(f) \leq \mu(\text{supp}(f))$.

Step 3: Realization as integration. Suppose $f \in C_c(X)$ and $0 \leq f \leq 1$.

$$\mu(f^{-1}(1)) \leq I(f) \leq \mu(f^{-1}(0)).$$

Step 4: Radonness. Trivial.

□
