Neural Networks

IKHAN CHOI

The AI paradigm changes when a new approximating method is discovered.

1. Update of parameters

1.1. Gradient descent method.

1.2. Back propagation. Backpropagation refers to algorithms to train the weight matrices for minimizing the cost function J, which does not depend explicitly on any variables except the last layer vector $a^{(n)}$. However, since J is a function of the weight matrices implicitly, via $a^{(n)}$, we may find the representation of the gradiant of J as viewing it as a function on the space of weight matrices of each given layer. In other words, we want to find the coefficients of the differential form dJ on the basis $\{dW_{ij}^{(n-1)}\}_{i,j}$, $\{dW_{jk}^{(n-2)}\}_{j,k}$, or $\{dW_{kl}^{(n-3)}\}_{k,l}$, and so on.

Recall the definitions:

$$a_i^{(n)} = \sigma \left(\sum_j W_{ij}^{(n-1)} a_j^{(n-1)} \right).$$

Since the derivative of the sigmoid function is given by $\sigma' = \sigma - \sigma^2$, we can compute the following auxiliary relations

$$\frac{\partial a_i^{(n)}}{\partial a_i^{(n-1)}} = h(a_i^{(n)}) W_{ij}^{(n-1)} \quad \text{and} \quad \frac{\partial a_i^{(n)}}{\partial W_{i'j}^{(n-1)}} = \delta_{ii'} h(a_i^{(n)}) a_j^{(n-1)},$$

where $h(x) = x - x^2$.

Then, we can compute

$$dJ = \sum_{i} \frac{\partial J}{\partial a_{i}^{(n)}} \sum_{j} \frac{\partial a_{i}^{(n)}}{\partial W_{ij}^{(n-1)}} dW_{ij}^{(n-1)} = \sum_{i,j} \frac{\partial J}{\partial a_{i}^{(n)}} h(a_{i}^{(n)}) a_{j}^{(n-1)} dW_{ij}^{(n-1)},$$

which implies

$$\nabla J(W^{(n-1)}) = \left[\frac{\partial J}{\partial a_i^{(n)}} h(a_i^{(n)}) a_j^{(n-1)}\right] \frac{\partial}{\partial W_{ij}^{(n-1)}}.$$

Note that it is a function of a_i and a_j . The gradient descent method will take

$$W_{ij}^{(n-1)^+} := W_{ij}^{(n-1)} - \alpha \cdot \frac{\partial J}{\partial a_i^{(n)}} h(a_i^{(n)}) a_j^{(n-1)}$$

with a proper parameter $\alpha > 0$.

Last Update: July 15, 2019.

By the same reason,

$$dJ = \sum_{i,j,k} \frac{\partial J}{\partial a_i^{(n)}} \frac{\partial a_i^{(n)}}{\partial a_j^{(n-1)}} \frac{\partial a_j^{(n-1)}}{\partial W_{jk}^{(n-2)}} dW_{jk}^{(n-2)}$$
$$= \sum_{i,j,k} \frac{\partial J}{\partial a_i^{(n)}} \cdot h(a_i^{(n)}) W_{ij}^{(n-1)} \cdot h(a_j^{(n-1)}) a_k^{(n-2)} dW_{jk}^{(n-2)},$$

which implies

$$\nabla J(W^{(n-2)}) = \left[\sum_{i} \frac{\partial J}{\partial a_{i}^{(n)}} \cdot h(a_{i}^{(n)}) W_{ij}^{(n-1)} \cdot h(a_{j}^{(n-1)}) a_{k}^{(n-2)} \right] \frac{\partial}{\partial W_{jk}^{(n-2)}}.$$

Therefore, the gradient descent method will take

$$\begin{split} W_{jk}^{(n-2)^{+}} &:= W_{jk}^{(n-2)} - \alpha \cdot \sum_{i} \frac{\partial J}{\partial a_{i}^{(n)}} h(a_{i}^{(n)}) W_{ij}^{(n-1)} h(a_{j}^{(n-1)}) a_{k}^{(n-2)} \\ &= W_{jk}^{(n-2)} + (1 - a_{j}^{(n-1)}) a_{k}^{(n-2)} \sum_{i} (W_{ij}^{(n-1)^{+}} - W_{ij}^{(n-1)}) W_{ij}^{(n-1)}. \end{split}$$

In similar way,

$$W_{kl}^{(n-3)^+} := W_{kl}^{(n-3)} + (1 - a_k^{(n-2)}) a_l^{(n-3)} \sum_i (W_{jk}^{(n-2)^+} - W_{jk}^{(n-2)}) W_{jk}^{(n-2)}(?)$$

2. Maximum likelihood estimate

Definition 2.1. Let f be a distribution function on a measure space X. Let $\{f_{\theta}\}_{\theta}$ be a parametrized family of distribution functions on X. The *likelihood* $L_n(\theta): \Omega^n \to \mathbb{R}_{\geq 0}$ for a fixed parameter θ is a random variable defined by

$$L_n(\theta) := \prod_{i=1}^n f_{\theta}(x_i)$$

where $\{x_i\}_i$ is a family of i.i.d. X-valued random variables with a distribution f.

The objective of the likelihood function is to find θ such that f_{θ} approximates the unknown distribution f. Write

$$\frac{1}{n}\log L_n(\theta) = \frac{1}{n}\sum_{i=1}^n \log f_{\theta}(x_i).$$

By the law of large numbers, $\frac{1}{n} \log L_n(\theta)$ converges to a constant function

$$\mathbb{E}(\log f_{\theta}(x)) = \int_{X} f \log f_{\theta}$$

in measure as $n \to \infty$. This constant function is exactly what we call *cross entropy*.

The Kullback-Leibler divergence is a kind of asymmetric distance function defined from the difference with cross entropy

$$D_{KL}(f||f_{\theta}) := \int_{X} f \log f - \int_{X} f \log f_{\theta}.$$

It is proved to be always nonnegative by the Jensen inequality:

$$\int_X f \log f_\theta - \int_X f \log f = \int_X f \log \frac{f_\theta}{f} \le \log \left(\int_X f \frac{f_\theta}{f} \right) = 0.$$

Here, we exclude the region f=0 from the integration region. Then, we can say, bigger $L_n(\theta)$ is, closer f_{θ} and f are.

3. Generative adversarial networks
